Chapter 1

BLR for general finite fields

1.1 BLR over General Finite Fields

Throughout this section, let $q = p^s$ for a prime p and $s \in \mathbb{N}$ with $s \geq 1$. All vectors are in $\mathbb{F}_q^n$, and all expectations are uniform over the indicated finite sets. Let $\omega_p = e^{2\pi i/p}$.

Definition 1.1.1 (Field trace). *The field trace $\text{Tr} : \mathbb{F}_q \rightarrow \mathbb{F}_p$ is*

$$\text{Tr}(z) := \sum_{i=0}^{s-1} z^{p^i}.$$

Definition 1.1.2 (Additive characters). *For $\alpha \in \mathbb{F}_q^n$, define the additive character $\chi_\alpha : \mathbb{F}_q^n \rightarrow \mathbb{C}$ by*

$$\chi_\alpha(x) := \omega_p^{\text{Tr}(\langle \alpha, x \rangle)},$$

where $\langle \alpha, x \rangle = \sum_{i=1}^n \alpha_i x_i \in \mathbb{F}_q$.

Definition 1.1.3 (Inner product and Fourier coefficient). *For functions $h_1, h_2 : \mathbb{F}_q^n \rightarrow \mathbb{C}$, define*

$$\langle h_1, h_2 \rangle := \mathbb{E}_{x \in \mathbb{F}_q^n} [h_1(x) \overline{h_2(x)}].$$

For $h : \mathbb{F}_q^n \rightarrow \mathbb{C}$ and $\alpha \in \mathbb{F}_q^n$, define

$$\hat{h}(\alpha) := \langle h, \chi_\alpha \rangle = \mathbb{E}_{x \in \mathbb{F}_q^n} [h(x) \overline{\chi_\alpha(x)}].$$

Lemma 1.1.4 (Character orthogonality). *For every $\alpha, \beta \in \mathbb{F}_q^n$,*

$$\mathbb{E}_{x \in \mathbb{F}_q^n} [\chi_\alpha(x) \overline{\chi_\beta(x)}] = \begin{cases} 1 & \text{if } \alpha = \beta, \\ 0 & \text{if } \alpha \neq \beta. \end{cases}$$

Equivalently, $\mathbb{E}_x [\chi_\alpha(x)] = 0$ for $\alpha \neq 0$ and equals 1 for $\alpha = 0$.

Proof. First observe that for every $\alpha, \beta \in \mathbb{F}_q^n$ and every $x \in \mathbb{F}_q^n$,

$$\chi_\alpha(x) \overline{\chi_\beta(x)} = \omega_p^{\text{Tr}(\langle \alpha, x \rangle)} \omega_p^{-\text{Tr}(\langle \beta, x \rangle)} = \omega_p^{\text{Tr}(\langle \alpha - \beta, x \rangle)} = \chi_{\alpha - \beta}(x),$$

where we used the $\mathbb{F}_p$ -linearity of the trace map.

If $\alpha = \beta$, then $\alpha - \beta = 0$, so $\chi_{\alpha-\beta}(x) = 1$ for every $x \in \mathbb{F}_q^n$. Hence

$$\mathbb{E}_{x \in \mathbb{F}_q^n} [\chi_\alpha(x) \overline{\chi_\beta(x)}] = \mathbb{E}_{x \in \mathbb{F}_q^n} [1] = 1.$$

Now suppose $\alpha \neq \beta$. Let $\gamma := \alpha - \beta$. Then $\gamma \neq 0$, so there exists an index j such that $\gamma_j \neq 0$. Fix all coordinates of x except x_j . For the fixed remaining coordinates, the map

$$x_j \mapsto \langle \gamma, x \rangle$$

has the form

$$x_j \mapsto \gamma_j x_j + c$$

for some constant $c \in \mathbb{F}_q$. Since $\gamma_j \neq 0$, multiplication by γ_j is a bijection on $\mathbb{F}_q$, and therefore the affine map $x_j \mapsto \gamma_j x_j + c$ is also a bijection on $\mathbb{F}_q$. Thus, as x_j ranges uniformly over $\mathbb{F}_q$, the value $\langle \gamma, x \rangle$ also ranges uniformly over $\mathbb{F}_q$. Averaging first over x_j and then over the remaining coordinates gives

$$\mathbb{E}_{x \in \mathbb{F}_q^n} [\chi_\gamma(x)] = \mathbb{E}_{t \in \mathbb{F}_q} [\omega_p^{\text{Tr}(t)}].$$

It remains to show that this last average is zero. The trace map $\text{Tr} : \mathbb{F}_q \rightarrow \mathbb{F}_p$ is a nonzero $\mathbb{F}_p$ -linear map, so every fiber of Tr has the same cardinality. Since $|\mathbb{F}_q| = q$ and $|\mathbb{F}_p| = p$, each fiber has cardinality q/p . Therefore

$$\begin{aligned} \mathbb{E}_{t \in \mathbb{F}_q} [\omega_p^{\text{Tr}(t)}] &= \frac{1}{q} \sum_{t \in \mathbb{F}_q} \omega_p^{\text{Tr}(t)} \\ &= \frac{1}{q} \sum_{r \in \mathbb{F}_p} \sum_{\substack{t \in \mathbb{F}_q \\ \text{Tr}(t)=r}} \omega_p^r \\ &= \frac{1}{q} \sum_{r \in \mathbb{F}_p} \frac{q}{p} \omega_p^r \\ &= \frac{1}{p} \sum_{r \in \mathbb{F}_p} \omega_p^r \\ &= 0, \end{aligned}$$

because the sum of all p -th roots of unity is zero. Hence, if $\alpha \neq \beta$, then

$$\mathbb{E}_{x \in \mathbb{F}_q^n} [\chi_\alpha(x) \overline{\chi_\beta(x)}] = 0.$$

Combining the two cases proves the stated orthogonality relation. The equivalent formulation follows by taking $\beta = 0$. $\square$

Lemma 1.1.5 (Fourier inversion and Parseval). *For every function $h : \mathbb{F}_q^n \rightarrow \mathbb{C}$,*

$$h(x) = \sum_{\alpha \in \mathbb{F}_q^n} \hat{h}(\alpha) \chi_\alpha(x) \quad \text{for every } x \in \mathbb{F}_q^n,$$

and

$$\sum_{\alpha \in \mathbb{F}_q^n} |\hat{h}(\alpha)|^2 = \mathbb{E}_{x \in \mathbb{F}_q^n} [|h(x)|^2].$$

In particular, if $|h(x)| = 1$ for every x , then $\sum_{\alpha \in \mathbb{F}_q^n} |\hat{h}(\alpha)|^2 = 1$.

Proof. By Lemma 1.1.4, the additive characters

$$\{\chi_\alpha : \alpha \in \mathbb{F}_q^n\}$$

are orthonormal with respect to the inner product

$$\langle h_1, h_2 \rangle = \mathbb{E}_{x \in \mathbb{F}_q^n} [h_1(x) \overline{h_2(x)}].$$

Moreover, these characters span the vector space of all complex-valued functions on $\mathbb{F}_q^n$. Indeed, there are exactly q^n characters, and the space of functions $\mathbb{F}_q^n \rightarrow \mathbb{C}$ has dimension q^n . Since the characters are nonzero and pairwise orthogonal, they are linearly independent. Hence they form an orthonormal basis.

Therefore every function $h : \mathbb{F}_q^n \rightarrow \mathbb{C}$ has a unique expansion in this basis:

$$h = \sum_{\alpha \in \mathbb{F}_q^n} c_\alpha \chi_\alpha$$

for some coefficients $c_\alpha \in \mathbb{C}$. Taking the inner product of both sides with χ_β , we obtain

$$\langle h, \chi_\beta \rangle = \sum_{\alpha \in \mathbb{F}_q^n} c_\alpha \langle \chi_\alpha, \chi_\beta \rangle.$$

By orthonormality, all terms in the sum vanish except the term $\alpha = \beta$, and $\langle \chi_\beta, \chi_\beta \rangle = 1$. Hence

$$\langle h, \chi_\beta \rangle = c_\beta.$$

By definition of the Fourier coefficient,

$$\hat{h}(\beta) = \langle h, \chi_\beta \rangle.$$

Thus $c_\beta = \hat{h}(\beta)$ for every $\beta \in \mathbb{F}_q^n$. Therefore

$$h = \sum_{\alpha \in \mathbb{F}_q^n} \hat{h}(\alpha) \chi_\alpha.$$

Evaluating this identity at $x \in \mathbb{F}_q^n$ gives the Fourier inversion formula

$$h(x) = \sum_{\alpha \in \mathbb{F}_q^n} \hat{h}(\alpha) \chi_\alpha(x).$$

It remains to prove Parseval's identity. Using the Fourier expansion and orthonormality, we compute

$$\begin{aligned} \mathbb{E}_x |h(x)|^2 &= \langle h, h \rangle \\ &= \left\langle \sum_{\alpha \in \mathbb{F}_q^n} \hat{h}(\alpha) \chi_\alpha, \sum_{\beta \in \mathbb{F}_q^n} \hat{h}(\beta) \chi_\beta \right\rangle \\ &= \sum_{\alpha, \beta \in \mathbb{F}_q^n} \hat{h}(\alpha) \overline{\hat{h}(\beta)} \langle \chi_\alpha, \chi_\beta \rangle. \end{aligned}$$

Again, by orthonormality, $\langle \chi_\alpha, \chi_\beta \rangle = 0$ when $\alpha \neq \beta$, and $\langle \chi_\alpha, \chi_\alpha \rangle = 1$. Hence the double sum reduces to

$$\mathbb{E}_x |h(x)|^2 = \sum_{\alpha \in \mathbb{F}_q^n} \hat{h}(\alpha) \overline{\hat{h}(\alpha)} = \sum_{\alpha \in \mathbb{F}_q^n} |\hat{h}(\alpha)|^2.$$

This proves Parseval's identity.

Finally, if $|h(x)| = 1$ for every $x \in \mathbb{F}_q^n$, then

$$\mathbb{E}_x |h(x)|^2 = \mathbb{E}_x 1 = 1.$$

Therefore Parseval gives

$$\sum_{\alpha \in \mathbb{F}_q^n} |\hat{h}(\alpha)|^2 = 1.$$

□

Definition 1.1.6 (Fourier expansion of a finite-field-valued function). *Let $f : \mathbb{F}_q^n \rightarrow \mathbb{F}_q$. For each $c \in \mathbb{F}_q^\times$, define*

$$\varphi_c(x) := \omega_p^{\text{Tr}(cf(x))}.$$

The Fourier expansion of f is the family

$$\{\varphi_c\}_{c \in \mathbb{F}_q^\times}.$$

Lemma 1.1.7 (Character-sum indicator). *For every $z \in \mathbb{F}_q$,*

$$\mathbb{1}[z = 0] = \frac{1}{q} \sum_{c \in \mathbb{F}_q} \omega_p^{\text{Tr}(cz)}.$$

Consequently, for every $u, v \in \mathbb{F}_q$,

$$\mathbb{1}[u = v] = \frac{1}{q} \sum_{c \in \mathbb{F}_q} \omega_p^{\text{Tr}(c(u-v))}.$$

Proof. Let

$$\psi(z) := \omega_p^{\text{Tr}(z)}$$

be the standard additive character of $\mathbb{F}_q$. We prove that, for every $t \in \mathbb{F}_q$,

$$\mathbb{1}[t = 0] = \frac{1}{q} \sum_{c \in \mathbb{F}_q} \psi(ct).$$

The desired statement follows by taking $t = u - v$.

If $t = 0$, then $ct = 0$ for every $c \in \mathbb{F}_q$, so

$$\frac{1}{q} \sum_{c \in \mathbb{F}_q} \psi(ct) = \frac{1}{q} \sum_{c \in \mathbb{F}_q} 1 = 1.$$

Now suppose $t \neq 0$. Then multiplication by t is a bijection $\mathbb{F}_q \rightarrow \mathbb{F}_q$, so

$$\sum_{c \in \mathbb{F}_q} \psi(ct) = \sum_{z \in \mathbb{F}_q} \psi(z).$$

We claim that the latter sum is 0. Let

$$S := \sum_{z \in \mathbb{F}_q} \psi(z).$$

Since $\text{Tr} : \mathbb{F}_q \rightarrow \mathbb{F}_p$ is a nonzero $\mathbb{F}_p$ -linear map, it is surjective. Hence there exists $a \in \mathbb{F}_q$ such that $\text{Tr}(a) = 1$. Using the bijection $z \mapsto z + a$, we get

$$S = \sum_{z \in \mathbb{F}_q} \psi(z + a) = \sum_{z \in \mathbb{F}_q} \omega_p^{\text{Tr}(z+a)} = \sum_{z \in \mathbb{F}_q} \omega_p^{\text{Tr}(z)} \omega_p^{\text{Tr}(a)} = \omega_p S.$$

Since $\omega_p \neq 1$, this implies $S = 0$. Therefore, when $t \neq 0$,

$$\frac{1}{q} \sum_{c \in \mathbb{F}_q} \psi(ct) = 0.$$

Combining the two cases gives

$$\mathbb{1}[t = 0] = \frac{1}{q} \sum_{c \in \mathbb{F}_q} \omega_p^{\text{Tr}(ct)}.$$

Substituting $t = u - v$, we obtain

$$\mathbb{1}[u = v] = \frac{1}{q} \sum_{c \in \mathbb{F}_q} \omega_p^{\text{Tr}(c(u-v))}.$$

□

Definition 1.1.8 (Relative Hamming distance). For $f, g : \mathbb{F}_q^n \rightarrow \mathbb{F}_q$, define

$$\delta(f, g) := \Pr_{x \in \mathbb{F}_q^n} [f(x) \neq g(x)].$$

Definition 1.1.9 (Linear functions). For $\alpha \in \mathbb{F}_q^n$, define $\ell_\alpha : \mathbb{F}_q^n \rightarrow \mathbb{F}_q$ by

$$\ell_\alpha(x) := \langle \alpha, x \rangle.$$

The set of linear functions is

$$\mathcal{LIN} := \{\ell_\alpha \mid \alpha \in \mathbb{F}_q^n\}.$$

The distance from $f : \mathbb{F}_q^n \rightarrow \mathbb{F}_q$ to linearity is

$$\delta(f, \mathcal{LIN}) := \min_{\alpha \in \mathbb{F}_q^n} \delta(f, \ell_\alpha).$$

Lemma 1.1.10 (Well-separatedness of $\mathcal{LIN}$). For any distinct $f, g \in \mathcal{LIN}$, one has $\delta(f, g) = 1 - 1/|\mathbb{F}|$.

Proof. Let $a, b \in \mathbb{F}^n$ be the unique vectors such that $f(x) = \langle a, x \rangle$ and $g(x) = \langle b, x \rangle$ for each x . Let $c = a - b$, which must be a non-zero vector. In particular, there exists $i \in [n]$ such that $c_i \neq 0$. Take any permutation $\sigma : [n] \rightarrow [n]$ such that $\sigma(i) = n$. Then

$$\begin{aligned} \delta(f, g) &= 1 - \Pr_{x \sim \mathbb{F}^n} [\langle c, x \rangle = 0] \\ &= 1 - \frac{1}{|\mathbb{F}|^{n-1}} \sum_{x_1, \dots, x_{n-1} \in \mathbb{F}} \frac{1}{|\mathbb{F}|} \sum_{x_n \in \mathbb{F}} \mathbb{1}[c_i \cdot x_n = - \sum_{j \in [n] \setminus i} c_j \cdot x_{\sigma(j)}] \\ &= 1 - \frac{1}{|\mathbb{F}|^{n-1}} \sum_{x_1, \dots, x_{n-1} \in \mathbb{F}} \frac{1}{|\mathbb{F}|} \sum_{x_n \in \mathbb{F}} \mathbb{1}[x_n = -c_i^{-1} \cdot \sum_{j \in [n] \setminus i} c_j \cdot x_{\sigma(j)}] \end{aligned}$$

where the last equality follows because $c_i \neq 0$. Now note that $\mathbb{1}[x_n = -c_i^{-1} \cdot \sum_{j \in [n] \setminus i} c_j \cdot x_{\sigma(j)}]$ evaluates to 1 for exactly one value of x_n . Thus we continue from above and get

$$\delta(f, g) = 1 - \frac{1}{|\mathbb{F}|^{n-1}} \sum_{x_1, \dots, x_{n-1} \in \mathbb{F}} \frac{1}{|\mathbb{F}|} = 1 - \frac{1}{|\mathbb{F}|}.$$

□

Lemma 1.1.11 (Distance formula). *Let $f, g : \mathbb{F}_q^n \rightarrow \mathbb{F}_q$. Let $\{\varphi_c\}_{c \in \mathbb{F}_q^\times}$ and $\{\gamma_c\}_{c \in \mathbb{F}_q^\times}$ be their Fourier expansions. Then*

$$\delta(f, g) = 1 - \frac{1}{q} \left(1 + \sum_{c \in \mathbb{F}_q^\times} \langle \varphi_c, \gamma_c \rangle \right).$$

Equivalently,

$$\delta(f, g) = 1 - \frac{1}{q} \left(1 + \sum_{c \in \mathbb{F}_q^\times} \sum_{\alpha \in \mathbb{F}_q^n} \widehat{\varphi}_c(\alpha) \overline{\widehat{\gamma}_c(\alpha)} \right).$$

Proof. By Theorem 1.1.7,

$$\Pr_x[f(x) = g(x)] = \mathbb{E}_x \left[\frac{1}{q} \sum_{c \in \mathbb{F}_q} \omega_p^{\text{Tr}(c(f(x) - g(x)))} \right].$$

The term $c = 0$ contributes $1/q$. For $c \neq 0$,

$$\omega_p^{\text{Tr}(c(f(x) - g(x)))} = \varphi_c(x) \overline{\gamma_c(x)}.$$

Therefore

$$\Pr_x[f(x) = g(x)] = \frac{1}{q} \left(1 + \sum_{c \in \mathbb{F}_q^\times} \langle \varphi_c, \gamma_c \rangle \right),$$

which gives the first formula after using $\delta(f, g) = 1 - \Pr_x[f(x) = g(x)]$. The second formula follows from Fourier inversion and Parseval. □

Lemma 1.1.12 (Fourier expansion of a linear function). *Fix $\alpha \in \mathbb{F}_q^n$ and $c \in \mathbb{F}_q^\times$. Let $\lambda_c(x) := \omega_p^{\text{Tr}(c\ell_\alpha(x))}$. Then*

$$\lambda_c = \chi_{c\alpha}.$$

Equivalently, for every $\beta \in \mathbb{F}_q^n$,

$$\widehat{\lambda}_c(\beta) = \begin{cases} 1 & \text{if } \beta = c\alpha, \\ 0 & \text{if } \beta \neq c\alpha. \end{cases}$$

Proof. For every $x \in \mathbb{F}_q^n$,

$$\lambda_c(x) = \omega_p^{\text{Tr}(c\langle \alpha, x \rangle)} = \omega_p^{\text{Tr}(\langle c\alpha, x \rangle)} = \chi_{c\alpha}(x).$$

The statement about Fourier coefficients follows from Theorem 1.1.4. □

Lemma 1.1.13 (Distance to linearity in Fourier form). *Let $f : \mathbb{F}_q^n \rightarrow \mathbb{F}_q$ have Fourier expansion $\{\varphi_c\}_{c \in \mathbb{F}_q^\times}$. Then*

$$\delta(f, \mathcal{LIN}) = 1 - \frac{1}{q} \left(1 + \max_{\alpha \in \mathbb{F}_q^n} \sum_{c \in \mathbb{F}_q^\times} \widehat{\varphi}_c(c\alpha) \right).$$

Moreover, for every $\alpha \in \mathbb{F}_q^n$, the quantity

$$S_\alpha := \sum_{c \in \mathbb{F}_q^\times} \widehat{\varphi}_c(c\alpha)$$

is real and satisfies $-1 \leq S_\alpha \leq q-1$.

Proof. Apply Theorem 1.1.11 with $g = \ell_\alpha$ and use Theorem 1.1.12. This gives

$$\delta(f, \ell_\alpha) = 1 - \frac{1}{q} \left(1 + \sum_{c \in \mathbb{F}_q^\times} \widehat{\varphi}_c(c\alpha) \right).$$

Taking the minimum over α gives the claimed formula for $\delta(f, \mathcal{LIN})$. For fixed α , the same formula expresses S_α as $q(1 - \delta(f, \ell_\alpha)) - 1$. Hence S_α is real, and since $0 \leq \delta(f, \ell_\alpha) \leq 1$, we get $-1 \leq S_\alpha \leq q-1$. $\square$

Definition 1.1.14 (Finite-field BLR test). *Given oracle access to $f : \mathbb{F}_q^n \rightarrow \mathbb{F}_q$, the finite-field BLR verifier V_{BLR}^f samples $a, b \in \mathbb{F}_q^\times$ and $x, y \in \mathbb{F}_q^n$ uniformly and accepts iff*

$$af(x) + bf(y) = f(ax + by).$$

That is,

$$V_{\text{BLR}}^f = 1 \iff af(x) + bf(y) = f(ax + by).$$

Lemma 1.1.15 (Completeness). *If $f \in \mathcal{LIN}$, then*

$$\Pr[V_{\text{BLR}}^f = 1] = 1.$$

Proof. If $f = \ell_\alpha$ for some $\alpha \in \mathbb{F}_q^n$, then for every $a, b \in \mathbb{F}_q^\times$ and $x, y \in \mathbb{F}_q^n$,

$$f(ax + by) = \langle \alpha, ax + by \rangle = a\langle \alpha, x \rangle + b\langle \alpha, y \rangle = af(x) + bf(y).$$

Thus the verifier accepts for every choice of randomness. $\square$

Lemma 1.1.16 (Exact BLR acceptance formula). *Let $f : \mathbb{F}_q^n \rightarrow \mathbb{F}_q$ have Fourier expansion $\{\varphi_c\}_{c \in \mathbb{F}_q^\times}$. For each $\alpha \in \mathbb{F}_q^n$, define*

$$S_\alpha := \sum_{c \in \mathbb{F}_q^\times} \widehat{\varphi}_c(c\alpha).$$

Then

$$\Pr[V_{\text{BLR}}^f = 1] = \frac{1}{q} \left(1 + \frac{1}{(q-1)^2} \sum_{\alpha \in \mathbb{F}_q^n} S_\alpha^3 \right).$$

Proof. By Theorem 1.1.7, for fixed a, b, x, y ,

$$\mathbb{1}[af(x) + bf(y) = f(ax + by)] = \frac{1}{q} \sum_{c \in \mathbb{F}_q} \omega_p^{\text{Tr}(c(af(x) + bf(y) - f(ax + by)))}.$$

Taking expectation gives

$$\Pr[V_{\text{BLR}}^f = 1] = \frac{1}{q} + \frac{1}{q} \mathbb{E}_{a,b,x,y} \left[\sum_{c \in \mathbb{F}_q^\times} \varphi_{ca}(x) \varphi_{cb}(y) \varphi_{-c}(ax + by) \right].$$

Expand the three complex-valued functions into their Fourier expansions:

$$\begin{aligned} & \mathbb{E}_{a,b,x,y} \left[\sum_{c \in \mathbb{F}_q^\times} \varphi_{ca}(x) \varphi_{cb}(y) \varphi_{-c}(ax + by) \right] \\ &= \mathbb{E}_{a,b} \left[\sum_{c \in \mathbb{F}_q^\times} \sum_{\alpha, \beta, \gamma \in \mathbb{F}_q^n} \widehat{\varphi_{ca}}(\alpha) \widehat{\varphi_{cb}}(\beta) \widehat{\varphi_{-c}}(\gamma) \mathbb{E}_{x,y} [\chi_\alpha(x) \chi_\beta(y) \chi_\gamma(ax + by)] \right]. \end{aligned}$$

Since

$$\chi_\gamma(ax + by) = \chi_{a\gamma}(x) \chi_{b\gamma}(y),$$

Theorem 1.1.4 implies that the inner expectation is 1 exactly when

$$\alpha + a\gamma = 0 \quad \text{and} \quad \beta + b\gamma = 0,$$

and is 0 otherwise. Therefore the last display equals

$$\mathbb{E}_{a,b} \left[\sum_{c \in \mathbb{F}_q^\times} \sum_{\alpha \in \mathbb{F}_q^n} \widehat{\varphi_{ca}}(\alpha) \widehat{\varphi_{cb}}(a^{-1}b\alpha) \widehat{\varphi_{-c}}(-a^{-1}\alpha) \right].$$

Substitute $\alpha = ca\eta$. Then this becomes

$$\mathbb{E}_{a,b} \left[\sum_{c \in \mathbb{F}_q^\times} \sum_{\eta \in \mathbb{F}_q^n} \widehat{\varphi_{ca}}(ca\eta) \widehat{\varphi_{cb}}(cb\eta) \widehat{\varphi_{-c}}(-c\eta) \right].$$

As a, b, c range over $\mathbb{F}_q^\times$, so do ca, cb , and $-c$. Hence this equals

$$\frac{1}{(q-1)^2} \sum_{\eta \in \mathbb{F}_q^n} \left(\sum_{d \in \mathbb{F}_q^\times} \widehat{\varphi_d}(d\eta) \right)^3 = \frac{1}{(q-1)^2} \sum_{\eta \in \mathbb{F}_q^n} S_\eta^3.$$

Substituting into the expression for $\Pr[V_{\text{BLR}}^f = 1]$ proves the claim. $\square$

Lemma 1.1.17 (Second moment bound). *With S_α as in Theorem 1.1.16,*

$$\sum_{\alpha \in \mathbb{F}_q^n} S_\alpha^2 \leq (q-1)^2.$$

Proof. Expanding the square gives

$$\sum_{\alpha \in \mathbb{F}_q^n} S_\alpha^2 = \sum_{a, b \in \mathbb{F}_q^\times} \sum_{\alpha \in \mathbb{F}_q^n} \widehat{\varphi}_a(a\alpha) \widehat{\varphi}_b(b\alpha).$$

For fixed $a, b \in \mathbb{F}_q^\times$, Cauchy–Schwarz and Theorem 1.1.5 give

$$\begin{aligned} \left| \sum_{\alpha \in \mathbb{F}_q^n} \widehat{\varphi}_a(a\alpha) \widehat{\varphi}_b(b\alpha) \right| &\leq \left(\sum_{\alpha \in \mathbb{F}_q^n} |\widehat{\varphi}_a(a\alpha)|^2 \right)^{1/2} \left(\sum_{\alpha \in \mathbb{F}_q^n} |\widehat{\varphi}_b(b\alpha)|^2 \right)^{1/2} \\ &= 1. \end{aligned}$$

The equality uses that multiplication by a and by b permutes $\mathbb{F}_q^n$, and that $|\varphi_a(x)| = |\varphi_b(x)| = 1$ for every x . Summing over the $(q-1)^2$ choices of (a, b) gives the result. $\square$

Theorem 1.1.18 (Soundness of the finite-field BLR test). *For every function $f : \mathbb{F}_q^n \rightarrow \mathbb{F}_q$,*

$$\Pr[\mathbf{V}_{\text{BLR}}^f = 0] \geq \delta(f, \mathcal{LIN}).$$

Equivalently,

$$\Pr[\mathbf{V}_{\text{BLR}}^f = 1] \leq 1 - \delta(f, \mathcal{LIN}).$$

Proof. Let S_α be as in Theorem 1.1.16, and let

$$M := \max_{\alpha \in \mathbb{F}_q^n} S_\alpha.$$

By Theorem 1.1.13,

$$1 - \delta(f, \mathcal{LIN}) = \frac{1}{q}(1 + M).$$

By Theorem 1.1.13, each S_α is real and $S_\alpha \leq M$. Therefore $S_\alpha^3 \leq MS_\alpha^2$ for every α , because $S_\alpha^2 \geq 0$. Using Theorem 1.1.16 and Theorem 1.1.17,

$$\begin{aligned} \Pr[\mathbf{V}_{\text{BLR}}^f = 1] &= \frac{1}{q} \left(1 + \frac{1}{(q-1)^2} \sum_{\alpha \in \mathbb{F}_q^n} S_\alpha^3 \right) \\ &\leq \frac{1}{q} \left(1 + \frac{M}{(q-1)^2} \sum_{\alpha \in \mathbb{F}_q^n} S_\alpha^2 \right) \\ &\leq \frac{1}{q}(1 + M) \\ &= 1 - \delta(f, \mathcal{LIN}). \end{aligned}$$

Taking complements gives $\Pr[\mathbf{V}_{\text{BLR}}^f = 0] \geq \delta(f, \mathcal{LIN})$. $\square$

Theorem 1.1.19 (Counterexample to the proposed cubic lower bound). *The inequality*

$$(1 - \delta(f, \mathcal{LIN}))^3 \leq \Pr[\mathbf{V}_{\text{BLR}}^f = 1]$$

does not hold for all functions $f : \mathbb{F}_q^n \rightarrow \mathbb{F}_q$ with the finite-field BLR verifier from Theorem 1.1.14.

Proof. It suffices to give a concrete counterexample. Take $q = 2$ and $n = 1$, so the domain and codomain are both $\mathbb{F}_2$. Let

$$f : \mathbb{F}_2 \rightarrow \mathbb{F}_2, \quad f(0) = 1, \quad f(1) = 1.$$

The homogeneous linear maps $\mathbb{F}_2 \rightarrow \mathbb{F}_2$ are exactly the zero map and the identity map. The function f agrees with the zero map at no point, and it agrees with the identity map only at the point 1. Hence

$$\delta(f, \mathcal{LIN}) = \frac{1}{2}, \quad 1 - \delta(f, \mathcal{LIN}) = \frac{1}{2}.$$

For the verifier, the only possible nonzero field elements are $a = b = 1$. Thus the verifier accepts on a pair (x, y) exactly when

$$f(x) + f(y) = f(x + y).$$

Since f is constantly 1, the left-hand side is $1 + 1 = 0$ in $\mathbb{F}_2$, while the right-hand side is 1. Therefore the verifier rejects for every choice of x, y , and

$$\Pr[V_{\text{BLR}}^f = 1] = 0.$$

But

$$(1 - \delta(f, \mathcal{LIN}))^3 = \left(\frac{1}{2}\right)^3 = \frac{1}{8} > 0 = \Pr[V_{\text{BLR}}^f = 1].$$

This contradicts the proposed lower bound. $\square$

Theorem 1.1.20 (Lower bound from agreement with a linear function). *Let $f : \mathbb{F}_q^n \rightarrow \mathbb{F}_q$. Suppose there exists $\ell \in \mathcal{LIN}$ such that*

$$\Pr_{x \in \mathbb{F}_q^n} [f(x) = \ell(x)] \geq 1 - \varepsilon.$$

Then

$$\Pr[V_{\text{BLR}}^f = 1] \geq 1 - 3\varepsilon + 2\varepsilon^2.$$

In particular,

$$\Pr[V_{\text{BLR}}^f = 1] \geq 1 - 3\delta(f, \mathcal{LIN}) + 2\delta(f, \mathcal{LIN})^2.$$

Proof. Let

$$G := \{z \in \mathbb{F}_q^n : f(z) = \ell(z)\}$$

be the agreement set, and let $B := \mathbb{F}_q^n \setminus G$ be the bad set. Write

$$\eta := \Pr_z[z \in B].$$

By assumption, $\eta \leq \varepsilon$.

The verifier samples $a, b \in \mathbb{F}_q^\times$ and $x, y \in \mathbb{F}_q^n$, and queries

$$x, \quad y, \quad ax + by.$$

For fixed $a, b \in \mathbb{F}_q^\times$, the random variables x , y , and $ax + by$ are each uniform on $\mathbb{F}_q^n$. Indeed, x and y are uniform by definition, and $ax + by$ is uniform because, after fixing a , b , and x , the map

$$y \mapsto ax + by$$

is a bijection of $\mathbb{F}_q^n$.

Therefore

$$\Pr[x \in B] = \Pr[y \in B] = \Pr[ax + by \in B] = \eta.$$

Moreover the three queried points are pairwise independent. For fixed $a, b \in \mathbb{F}_q^\times$, each of the maps

$$(x, y) \mapsto (x, y), \quad (x, y) \mapsto (x, ax + by), \quad (x, y) \mapsto (y, ax + by)$$

is a bijection from $\mathbb{F}_q^n \times \mathbb{F}_q^n$ to itself. Hence

$$\Pr[x \in B, y \in B] = \Pr[x \in B, ax + by \in B] = \Pr[y \in B, ax + by \in B] = \eta^2.$$

By inclusion–exclusion and the trivial bound

$$\Pr[x \in B, y \in B, ax + by \in B] \leq \Pr[x \in B, y \in B] = \eta^2,$$

we get

$$\Pr[x \in B \text{ or } y \in B \text{ or } ax + by \in B] \leq 3\eta - 3\eta^2 + \eta^2 = 3\eta - 2\eta^2.$$

On the complementary event, the verifier sees the same three values as it would see from ℓ :

$$f(x) = \ell(x), \quad f(y) = \ell(y), \quad f(ax + by) = \ell(ax + by).$$

Since ℓ is linear,

$$\ell(ax + by) = a\ell(x) + b\ell(y).$$

Thus

$$f(ax + by) = af(x) + bf(y),$$

so the verifier accepts. Hence the acceptance probability is at least the probability of the complementary event:

$$\Pr[V_{\text{BLR}}^f = 1] \geq 1 - 3\eta + 2\eta^2.$$

If $\varepsilon \geq 1/2$, then $1 - 3\varepsilon + 2\varepsilon^2 \leq 0$, so the desired bound is trivial. Otherwise $\varepsilon \leq 1/2$, and since $\eta \leq \varepsilon$, the function $1 - 3t + 2t^2$ is decreasing on the interval containing both η and ε . This gives

$$\Pr[V_{\text{BLR}}^f = 1] \geq 1 - 3\varepsilon + 2\varepsilon^2.$$

Taking ℓ to be a closest linear function gives the final statement with $\varepsilon = \delta(f, \mathcal{LIN})$. $\square$

Theorem 1.1.21 (Boolean tightness for subspace error sets). *The bound in Theorem 1.1.20 is tight for the Boolean BLR test for infinitely many values of ε . More precisely, let $q = 2$ and let $B \leq \mathbb{F}_2^n$ be a linear subspace of density $\varepsilon = 2^{-k}$. Define*

$$f : \mathbb{F}_2^n \rightarrow \mathbb{F}_2, \quad f(x) = \begin{cases} 1 & \text{if } x \in B, \\ 0 & \text{if } x \notin B. \end{cases}$$

Then $\delta(f, \mathcal{LIN}) = \varepsilon$ and

$$\Pr[V_{\text{BLR}}^f = 1] = 1 - 3\varepsilon + 2\varepsilon^2.$$

Proof. The zero linear function disagrees with f exactly on B , so $\delta(f, \mathcal{LIN}) \leq \varepsilon$. If $m : \mathbb{F}_2^n \rightarrow \mathbb{F}_2$ is any nonzero linear function, then m is balanced. Thus m agrees with the indicator of B on at most half of the domain, whereas the zero linear function agrees on a $1 - \varepsilon$ fraction of the domain. For $\varepsilon \leq 1/2$, this shows that the closest linear function is the zero function, so $\delta(f, \mathcal{LIN}) = \varepsilon$.

Since $q = 2$, the verifier has $a = b = 1$ and accepts iff

$$f(x) + f(y) = f(x + y).$$

Because B is a subspace, among the three points x , y , and $x + y$, the number lying in B is never exactly two. Therefore the verifier rejects exactly when at least one of the three queried points lies in B .

The three events

$$x \in B, \quad y \in B, \quad x + y \in B$$

each have probability ε , and each pair has probability ε^2 . Since B is a subspace, the triple event also has probability ε^2 : if $x, y \in B$, then $x + y \in B$. Hence

$$\Pr[V_{\text{BLR}}^f = 0] = 3\varepsilon - 3\varepsilon^2 + \varepsilon^2 = 3\varepsilon - 2\varepsilon^2.$$

Taking complements gives

$$\Pr[V_{\text{BLR}}^f = 1] = 1 - 3\varepsilon + 2\varepsilon^2.$$

□

Chapter 2

Gowers Hatami theorem

2.1 Preliminaries

Definition 2.1.1 (σ inner product.). *The σ inner product between matrices A and B is defined as*

$$\langle A, B \rangle_\sigma = \text{Tr}(A^* B \sigma), \quad (2.1)$$

where $\sigma \geq 0$ and A^* denotes conjugate-transpose.

Definition 2.1.2 ((ϵ, σ) -representation.). *Given a finite group G , an integer $d \geq 1, \epsilon \geq 0$, and a d -dimensional positive semidefinite matrix σ with trace 1, an (ϵ, σ) -representation of G is a map $f : G \rightarrow U_d(\mathbb{C})$, to the $d \times d$ unitary matrices, such that*

$$\mathbb{E}_{x, y \in G} \Re \left(\langle f(x)^* f(y), f(x^{-1}y) \rangle_\sigma \right) \geq 1 - \epsilon, \quad (2.2)$$

where $\Re$ denotes taking real part of the inner product.

Proposition 2.1.3. *Let G be a finite group, and let $f, f_2 : G \rightarrow U(n)$ be functions into the unitary matrices. Then*

$$\mathbb{E}_{x \in G} \|f(x) - f_2(x)\|_\sigma^2 \leq 2\epsilon \iff \mathbb{E}_{x \in G} \Re(\langle f(x), f_2(x) \rangle_\sigma) \geq 1 - \epsilon.$$

Proof. For unitary matrices A, B , we have

$$\|A - B\|_\sigma^2 = 2 - 2\Re \langle A, B \rangle_\sigma. \quad (2.3)$$

Since $\mathbb{E}$ is linear, this proves the proposition. $\square$

TODO:

- Relation to classical BLR test

2.2 Representation theory

Definition 2.2.1 (Unitary Representation). *A unitary representation of G is a representation to unitary matrices $\rho : G \rightarrow U(V)$.*

Definition 2.2.2 (Regular representation). *Let $R : G \rightarrow \mathbb{C}[G]$ be a regular representation where $\{|g\rangle, g \in G\}$ forms a basis of $\mathbb{C}[G]$. The representation is given by*

$$R(x)|g\rangle = |xg\rangle. \quad (2.4)$$

It is possible to decompose any representation of a finite group into direct sums over irreps.

Theorem 2.2.3 (Maschke's theorem). *Let G be a finite group and let $\rho : G \rightarrow \text{GL}(V)$ be a finite-dimensional representation over $\mathbb{C}$. Then ρ is completely reducible. In particular, there exists a decomposition*

$$\rho \cong \bigoplus_m r_m \rho_m, \quad (2.5)$$

where $\{\rho_m\}$ is a set of inequivalent irreducible representations of G , and $r_m \in \mathbb{Z}^+$ are the multiplicities.

Proof sketch. Maschke's theorem is partially formalized in `Mathlib.RepresentationTheory.Maschke` but incomplete. Jonathan's team is formalizing this. $\square$

Proposition 2.2.4 (Decomposition of the regular representation). *Let $R : G \rightarrow \text{GL}(\mathbb{C}[G])$ be the regular representation of a finite group G . Then*

$$R \cong \bigoplus_{\rho \in \widehat{G}} d_\rho \rho, \quad (2.6)$$

where $\widehat{G}$ is a complete set of inequivalent irreducible representations of G , and $d_\rho = \dim(V_\rho)$ is the dimension of ρ .

Proof sketch. This can be proven using Maschke's theorem in 2.2.3 to decompose into irreps with multiplicity. Then use character orthogonality theorem in `mathlib.FDRep.char_orthonormal` to show the multiplicity equals irrep dimension. A more formal statement is given by the Peter-Weyl theorem. $\square$

Proposition 2.2.5 (Character of regular representation). *Let G be a finite group and $\sum_\rho$ denotes summing over the complete set of inequivalent irreps $\widehat{G}$*

$$\sum_{\rho \in \widehat{G}} d_\rho \text{Tr}(\rho(x)) = |G| \delta_{x,e}. \quad (2.7)$$

Proof sketch. The proof uses decomposition of regular representation and definition of character. $\square$

Definition 2.2.6 (Group fourier transform). *Let $f : G \rightarrow U_d(\mathbb{C})$ be a map and $\rho : G \rightarrow U_{d_\rho}(\mathbb{C})$ be a unitary irrep. The fourier transform of f at the representation ρ is denoted by $\hat{f}$:*

$$\hat{f}(\rho) = \mathbb{E}_{x \in G} f(x) \otimes \overline{\rho(x)}, \quad (2.8)$$

where $\overline{\rho(x)}$ denotes complex conjugate of $\rho(x)$.

2.3 Gowers Hatami Theorem

Theorem 2.3.1 (Gowers-Hatami). *Let G be a finite group, $\varepsilon \geq 0$, and $f : G \rightarrow U_d(\mathbb{C})$ an (ε, σ) -representation of G . Then there exists a $d' \geq d$, an isometry $V : \mathbb{C}^d \rightarrow \mathbb{C}^{d'}$, and a representation $g : G \rightarrow U_{d'}(\mathbb{C})$ such that*

$$\mathbb{E}_{x \in G} \|f(x) - V^*g(x)V\|_\sigma^2 \leq 2\varepsilon. \quad (2.9)$$

Proof sketch. The full proof can be found in the lecture notes Theorem 2.3 [?]. In particular, the proof is constructive. The isometry is defined as $V : \mathbb{C}^d \rightarrow \mathbb{C}^d \otimes (\oplus_\rho \mathbb{C}^{d_\rho} \otimes \mathbb{C}^{d_\rho})$ by

$$Vu = \bigoplus_\rho d_\rho^{1/2} \sum_{i=1}^{d_\rho} (\hat{f}(\rho)(u \otimes e_i)) \otimes e_i. \quad (2.10)$$

And the exact representation is defined as

$$g(x) = \bigoplus_\rho (I_d \otimes I_{d_\rho} \otimes \rho(x)). \quad (2.11)$$

The proof requires the following two ingredients:

1. V is an isometry:

$$V^*V = \mathbb{I}_d \quad (2.12)$$

2. The isometry “averages” over group multiplication. For any $x \in G$,

$$V^*g(x)V = \mathbb{E}_z f(z)^* f(zx). \quad (2.13)$$

Both ingredients follow from the key identity over the regular representation in Eq. (2.7). $\square$

Next, we will give a different proof that does not directly decompose into irreps but instead uses the action of the regular representation.

Lemma 2.3.2 (Gowers-Hatami-Correlation). *Let G be a finite group, $\varepsilon \geq 0$, and $\rho : G \rightarrow U(\mathcal{H})$ an (ε, σ) -representation of G on space $\mathcal{H}$. Then there exists an isometry $V : \mathcal{H} \rightarrow \mathcal{H}'$ to a different space $\mathcal{H}'$, and a representation $\rho' : G \rightarrow \mathcal{H}'$ such that the average correlation between ρ and ρ' is:*

$$\mathbb{E}_{x \in G} \Re \langle f(x), V^* \rho'(x)V \rangle_\sigma \geq 1 - \varepsilon, \quad (2.14)$$

Proof. Here $\mathcal{H}' = L(G, \mathcal{H})$ is the space of functions $f : G \rightarrow \mathcal{H}$.

Let the isometry be defined by the action of the approximate representation on a state $u \in \mathcal{H}$ as

$$V : \mathcal{H} \rightarrow L(G, \mathcal{H}), \quad (2.15)$$

$$V(u) : G \rightarrow \mathcal{H}, \quad x \mapsto \rho(x)(u), \forall x \in G. \quad (2.16)$$

The adjoint map V^* is defined as the unique map such that for all $u \in \mathcal{H}$ and $g \in L(G, \mathcal{H})$,

$$\langle V(u), g \rangle_{L(G, \mathcal{H})} = \langle u, V^*(g) \rangle_{\mathcal{H}}. \quad (2.17)$$

In particular, V^* is explicitly given by the group average

$$V^* : L(G, \mathcal{H}) \rightarrow \mathcal{H}, \quad (2.18)$$

$$V^*(f) = \mathbb{E}_{x \in G} [\rho^*(x)f(x)]. \quad (2.19)$$

The exact representation is given by the right regular representation on $L(G, \mathcal{H})$:

$$\rho' : G \rightarrow \text{End}(L(G, \mathcal{H})), \quad (2.20)$$

$$(\rho'(x)f)(y) = f(yx), \quad \forall x, y \in G. \quad (2.21)$$

V is an isometry because

$$V^*V(u) = \mathbb{E}_{x \in G} [\rho^*(x)\rho(x)(u)] = u. \quad (2.22)$$

The isometry “averages” over group multiplication because

$$\begin{aligned} V^*\rho'(x)V(u) &= \mathbb{E}_{y \in G} [\rho^*(y)(\rho'(x)\rho(y))(u)] \\ &= \mathbb{E}_{y \in G} [\rho^*(y)(\rho(yx)(u))]. \end{aligned} \quad (2.23)$$

Finally, using the isometry average property in Eq. 2.23 and the definition of (ε, σ) -representation, we have

$$\begin{aligned} &\mathbb{E}_{x \in G} \Re \langle \rho(x), V^*\rho'(x)V \rangle_\sigma, \\ &= \mathbb{E}_{x, y \in G} \Re \langle \rho(x), \rho^*(y)\rho(yx) \rangle_\sigma, \\ &\geq 1 - \varepsilon. \end{aligned} \quad (2.24)$$

□

Theorem 2.3.3 (Gowers-Hatami-2). *Let G be a finite group, $\varepsilon \geq 0$, and $\rho : G \rightarrow U(\mathcal{H})$ an (ε, σ) -representation of G on space $\mathcal{H} = \mathbb{C}^d$. Then there exists an isometry $V : \mathcal{H} \rightarrow \mathcal{H}'$ to a different space $\mathcal{H}'$, and a representation $\rho' : G \rightarrow \mathcal{H}'$ such that*

$$\mathbb{E}_{x \in G} \|\rho(x) - V^*\rho'(x)V\|_\sigma^2 \leq 2\varepsilon. \quad (2.25)$$

Proof. A different proof of the Gowers-Hatami theorem is given in M. de la Salle’s notes [?].

The rest of the proof follows by expanding the σ -norm, bounding the norm of $\mathbb{E}_{x \in G} V^*\rho'(x)V$ and applying the definition of (ε, σ) -representation. In particular, we have

$$\begin{aligned} &\mathbb{E}_{x \in G} \|\rho(x) - V^*\rho'(x)V\|_\sigma^2 \\ &= \mathbb{E}_{x \in G} \|\rho(x)\|_\sigma^2 + \mathbb{E}_{x \in G} \|V^*\rho'(x)V\|_\sigma^2 - 2\mathbb{E}_{x \in G} \Re \langle \rho(x), V^*\rho'(x)V \rangle_\sigma \end{aligned} \quad (2.26)$$

Because ρ is unitary, $\mathbb{E}_{x \in G} \|\rho(x)\|_\sigma^2 = 1$. For the second term, since ρ' is unitary and V is an isometry,

$$\begin{aligned} &\mathbb{E}_{x \in G} \|V^*\rho'(x)V\|_\sigma^2 \\ &= \mathbb{E}_{x \in G} \text{Tr} [V^*\rho'^*(x)VV^*\rho'(x)V\sigma] \\ &= \mathbb{E}_{x, y, z \in G} \text{Tr} [\rho^*(yx)\rho(y)\rho^*(z)\rho(zx)\sigma] \end{aligned} \quad (2.27)$$

Because ρ is unitary the product $U(x, y, z) := \rho^*(yx)\rho(y)\rho^*(z)\rho(zx)$ is again a unitary operator, the above expression is upper bounded by Holder’s inequality as

$$\begin{aligned} &\mathbb{E}_{x, y, z \in G} \text{Tr} [U(x, y, z)\sigma] \\ &\leq \mathbb{E}_{x, y, z \in G} \|U(x, y, z)\|_\infty \|\sigma\|_1 = 1. \end{aligned} \quad (2.28)$$

Therefore using the bounds in Eq. 2.28 and Eq. 2.24 by applying Lemma 2.3.2, we have

$$\mathbb{E}_{x \in G} \|\rho(x) - V^*\rho'(x)V\|_\sigma^2 \leq 2 - 2(1 - \varepsilon) = 2\varepsilon. \quad (2.29)$$

□

2.4 Gowers-Hatami for classical BLR

In classical BLR, the mapping is from a field $\mathbb{F}_2^n$. First let us relate the BLR test to the notion of approximate representation.

Proposition 2.4.1 (BLR test induces an approximate representation). *Let $f : \mathbb{Z}_2^n \rightarrow \mathbb{Z}_2$ satisfy*

$$\Pr_{x,y}[f(x) + f(y) = f(x+y)] \geq 1 - \epsilon.$$

Define $F : \mathbb{Z}_2^n \rightarrow \{\pm 1\}$ by $F(x) = (-1)^{f(x)}$. Then

$$\mathbb{E}_{x,y}|F(x)F(y) - F(x+y)|^2 \leq 4\epsilon,$$

so F is an $(2\epsilon, 1)$ -approximate representation.

Proof. First observe that for all $x, y \in G$,

$$F(x)F(y) = (-1)^{f(x)+f(y)}.$$

Hence

$$F(x)F(y) = F(x+y) \iff f(x) + f(y) = f(x+y) \pmod{2}.$$

Define the indicator of BLR success:

$$\mathbf{1}_{\text{good}}(x, y) := \mathbf{1}[f(x) + f(y) = f(x+y)].$$

Then

$$\Pr_{x,y}[\mathbf{1}_{\text{good}} = 1] \geq 1 - \epsilon.$$

Now compute the squared error. Since $F(x) \in \{\pm 1\}$,

$$|F(x)F(y) - F(x+y)|^2 = \begin{cases} 0 & \text{if } F(x)F(y) = F(x+y), \\ 4 & \text{otherwise.} \end{cases}$$

Taking expectation over (x, y) ,

$$\begin{aligned} \mathbb{E}_{x,y}|F(x)F(y) - F(x+y)|^2 &= 4 \Pr_{x,y}[F(x)F(y) \neq F(x+y)] \\ &= 4 \Pr_{x,y}[f(x) + f(y) \neq f(x+y)] \\ &\leq 4\epsilon. \end{aligned}$$

□

The Gowers-Hatami theorem can be applied to show that if a function $f : \mathbb{Z}_2^n \rightarrow \mathbb{F}_2$ passes the BLR linearity test with high probability, then there exists a linear function $\ell : \mathbb{F}_2^n \rightarrow \mathbb{F}_2$ that is close to f in terms of Hamming distance $\delta(f, \ell)$ defined in Def. 1.1.8. To do this, we first need to apply the Gowers-Hatami theorem to the approximate representation $F(x) = (-1)^{f(x)}$ given by Proposition 2.4.1.

Corollary 2.4.2 (Gowers-Hatami Correlation for BLR). *Let $F : \mathbb{Z}_2^n \rightarrow U(1)$ be an (ϵ, σ) approximate representation. Then there exists a unit vector v and an exact representation G such that*

$$\mathbb{E}_{x \in \mathbb{Z}_2^n} \Re \langle F(x), \langle v, G(x)v \rangle \rangle \geq 1 - \epsilon. \quad (2.30)$$

Next, we would like to conclude from the above corollary that there exists a linear function $\ell : \mathbb{Z}_2^n \rightarrow \mathbb{Z}_2$ such that $\Pr_x[f(x) \neq \ell(x)] \leq \epsilon/2$. To do this, we need to use a fact that about the regular representation of $\mathbb{Z}_2^n$.

Fact 2.4.3 (Regular representation of $\mathbb{Z}_2^n$). *Let $\rho(a)$ act on $L = \{f : \mathbb{Z}_2^n \rightarrow \mathbb{C}\}$ by $(\rho(a)f)(x) = f(x+a)$. Then in the Fourier basis $\{|S\rangle\}$, we have*

$$\rho(a) = \sum_{S \subseteq [n]} \chi_S(a) |S\rangle \langle S|.$$

Lemma 2.4.4 (Gowers-Hatami implies near linearity). *Let $F : \mathbb{Z}_2^n \rightarrow \mathbb{C}$ be an $(\epsilon, 1)$ approximate representation of $\mathbb{Z}_2^n$ from the BLR test such that $F(x) = (-1)^{f(x)}$ for some function $f : \mathbb{Z}_2^n \rightarrow \mathbb{Z}_2$. Then there exists a linear function $\ell : \mathbb{F}_2^n \rightarrow \mathbb{F}_2$ such that the distance between f and ℓ is bounded*

$$\delta(f, \ell) \leq \epsilon/2. \quad (2.31)$$

Proof. By Corollary 2.4.2, there exists a representation G and a unit vector v such that

$$\mathbb{E}_x \Re \langle F(x), \langle v, G(x)v \rangle \rangle \geq 1 - \epsilon.$$

Using the diagonal form of $G(x)$ in the character basis,

$$G(x) = \sum_S \chi_S(x) |S\rangle \langle S|.$$

The inner product condition can be rewritten as

$$\sum_S p_S \mathbb{E}_x \Re \langle F(x), \chi_S(x) \rangle \geq 1 - \epsilon,$$

where $p_S := |\langle v | S \rangle|^2$ and $\sum_S p_S = 1$. Therefore,

$$\sum_S p_S \widehat{F}(S) \geq 1 - \epsilon,$$

where $\widehat{F}(S) := \mathbb{E}_x[F(x)\chi_S(x)]$ is the real-valued Fourier coefficient of F at S .

Since $(p_S)_S$ is a probability distribution, there exists some S^* such that

$$\widehat{F}(S^*) \geq 1 - \epsilon.$$

This means that there is a large Fourier coefficient at S^* . Define $\ell(x) = x \cdot S^*$. Then $\chi_{S^*}(x) = (-1)^{\ell(x)}$, and

$$\mathbb{E}_x[F(x)\chi_{S^*}(x)] = 1 - 2\Pr_x[f(x) \neq \ell(x)].$$

Hence

$$1 - 2\delta(f, \ell) \geq 1 - \epsilon,$$

which implies

$$\delta(f, \ell) \leq \epsilon/2.$$

□

Proposition 2.4.5 (Equivalence for BLR test). *Let $\Pr[V_{BLR}^f = 0]$ denote the probability that the BLR verifier rejects a function $f : \mathbb{F}_2^n \rightarrow \mathbb{F}_2$. Let $\delta(f, \mathcal{LIN})$ denote the distance between f and the closest linear function in $\mathcal{LIN}$. Then the following statements are equivalent:*

- If $\Pr[V_{BLR}^f = 0] \leq \epsilon$, then $\delta(f, \mathcal{LIN}) \leq \epsilon$.
- $\Pr[V_{BLR}^f = 0] \geq \delta(f, \mathcal{LIN})$.

Now we provide the proof of Soundness of BLR test using the Gowers-Hatami theorem.

Theorem 2.4.6 (Soundness of the $\mathbb{Z}_2$ BLR). *For every function $f : \mathbb{F}_2^n \rightarrow \mathbb{F}_2$,*

$$\Pr[V_{BLR}^f = 0] \geq \delta(f, \mathcal{LIN}).$$

Equivalently,

$$\Pr[V_{BLR}^f = 1] \leq 1 - \delta(f, \mathcal{LIN}).$$

Proof. Let $F : \mathbb{Z}_2^n \rightarrow \{-1, 1\}$ be defined by $F(x) = (-1)^{f(x)}$, as given by Proposition 2.4.1. F is an $(2\epsilon, 1)$ approximate representation of $\mathbb{Z}_2^n$. Applying Gowers-Hatami theorem by Lemma 2.4.4, then there exists a linear function ℓ such that $\delta(f, \ell) \leq \epsilon$ so that $\delta(f, \mathcal{LIN}) \leq \epsilon$.

This proves the implication $\Pr[V_{BLR}^f = 0] \leq \epsilon \Rightarrow \delta(f, \mathcal{LIN}) \leq \epsilon$, which is equivalent to

$$\Pr[V_{BLR}^f = 0] \geq \delta(f, \mathcal{LIN}),$$

by Proposition 2.4.5. □

Chapter 3

Exponential-length PCP

Definition 3.0.1. A system of m quadratic equations in n variables over a field $\mathbb{F}$ is a list of polynomials $p_1, \dots, p_m \in \mathbb{F}[x_1, \dots, x_n]$ where each p_i has total degree at most 2.

$$\text{QESAT}(\mathbb{F}, n) := \{(p_1, \dots, p_m) \mid \exists a_1, \dots, a_n \in \mathbb{F}, \forall i \in [m], p_i(a_1, \dots, a_n) = 0\}.$$

For example, $(x + 1, xy + z) \in \text{QESAT}(\mathbb{F}_2, 3)$.

Definition 3.0.2. A PCP verifier is a probabilistic oracle Turing machine V with query access to a function $\pi : [\ell(|x|)] \rightarrow \Sigma$.

Definition 3.0.3. A language $L \subseteq \{0, 1\}^*$ is in $\text{PCP}[\varepsilon_c, \varepsilon_s, \Sigma, \ell, q, r]$ if there exists a polynomial-time PCP verifier V such that for every $x \in \{0, 1\}^*$, V makes at most $q(|x|)$ queries to the proof oracle, uses at most $r(|x|)$ bits of randomness, and the following holds:

- *Completeness:* If $x \in L$, then $\exists \pi \in \Sigma^{\ell(|x|)}, \Pr[V^\pi(x) = 1] \geq 1 - \varepsilon_c$.
- *Soundness:* If $x \notin L$, then $\forall \tilde{\pi} \in \Sigma^{\ell(|x|)}, \Pr[V^{\tilde{\pi}}(x) = 1] \leq \varepsilon_s$.

The following theorem is the main goal of this chapter.

Theorem 3.0.4.

$$\text{QESAT}(\mathbb{F}_2, n) \in \text{PCP}[\varepsilon_c = 0, \varepsilon_s = 1/2, \Sigma = \mathbb{F}_2, \ell = 2^{|x|}, q = O(1), r = |x|^{O(1)}].$$

Proof. TODO □

Definition 3.0.5. A LPCP verifier is a probabilistic oracle Turing machine V with query access to a linear function $\langle \pi, \cdot \rangle : \Sigma^{\ell(|x|)} \rightarrow \Sigma$.

Definition 3.0.6. A language $L \subseteq \{0, 1\}^*$ is in $\text{LPCP}[\varepsilon_c, \varepsilon_s, \Sigma, \ell, q, r]$ if there exists a polynomial-time LPCP verifier V such that for every $x \in \{0, 1\}^*$, V makes at most $q(|x|)$ queries to the linear proof oracle, uses at most $r(|x|)$ bits of randomness, and the following holds:

- *Completeness:* If $x \in L$, then $\exists \pi \in \Sigma^{\ell(|x|)}, \Pr[V^{\langle \pi, \cdot \rangle}(x) = 1] \geq 1 - \varepsilon_c$.
- *Soundness:* If $x \notin L$, then $\forall \tilde{\pi} \in \Sigma^{\ell(|x|)}, \Pr[V^{\langle \tilde{\pi}, \cdot \rangle}(x) = 1] \leq \varepsilon_s$.

3.1 Simpler BLR verifier for $\mathbb{F}_2$

Definition 3.1.1. Let $V_{\text{BLR}(\mathbb{F}_2, n)}^f$ be the verifier with oracle access to $f : \mathbb{F}_2^n \rightarrow \mathbb{F}_2$ defined as follows:

1. Sample $x, y \leftarrow \mathbb{F}_2^n$.
2. Accept if and only if $f(x) + f(y) = f(x + y)$.

Theorem 3.1.2. Let $n > 0$. For every linear function $f : \mathbb{F}_2^n \rightarrow \mathbb{F}_2$, we have

$$\Pr [V_{\text{BLR}(\mathbb{F}_2, n)}^f = 1] = 1.$$

Proof. □

Theorem 3.1.3. Let $n > 0$ and $f : \mathbb{F}_2^n \rightarrow \mathbb{F}_2$.

$$\Pr [V_{\text{BLR}(\mathbb{F}_2, n)}^f = 0] \geq \Delta(f, \mathcal{LIN}).$$

Proof. □

3.2 Linear PCP for linear equations

Definition 3.2.1. For a field $\mathbb{F}$ and parameters $m, n \in \mathbb{N}$, we define the language

$$\text{LINEQ}(\mathbb{F}, m, n) := \{(M, c) \in \mathbb{F}^{m \times n} \times \mathbb{F}^m \mid \exists b \in \mathbb{F}^n, Mb = c\}.$$

Definition 3.2.2. Let $V_{\text{LINEQ}(\mathbb{F}, m, n)}^{(b, \cdot)}$ be the LPCP verifier defined as follows:

1. Sample $r \leftarrow \mathbb{F}^m$.
2. Query $b \in \mathbb{F}^n$ at $u := M^\top r \in \mathbb{F}^n$.
3. Accept if and only if $\langle b, u \rangle = \langle c, r \rangle$.

Theorem 3.2.3.

$$\text{LINEQ}(\mathbb{F}, m, n) \in \text{LPCP} [\varepsilon_c = 0, \varepsilon_s = 1/|\mathbb{F}|, \Sigma = \mathbb{F}, \ell = |x|, q = 1, r = m \log |\mathbb{F}|].$$

Proof. Consider the LPCP verifier $V_{\text{LINEQ}(\mathbb{F}, m, n)}^{(b, \cdot)}(M, c)$.

Completeness: If $Mb = c$, then for every $r \in \mathbb{F}^m$, we have

$$\langle b, u \rangle = b^\top (M^\top r) = (Mb)^\top r = \langle c, r \rangle.$$

Soundness: If $Mb \neq c$, then

$$\begin{aligned} \Pr_{r \leftarrow \mathbb{F}^m} [\langle b, u \rangle = \langle c, r \rangle] &= \Pr_{r \leftarrow \mathbb{F}^m} [\langle Mb, r \rangle = \langle c, r \rangle] \\ &= \Pr_{r \leftarrow \mathbb{F}^m} \left[\sum_{i=1}^m (Mb - c)_i \cdot r_i = 0 \right] \leq 1/|\mathbb{F}|, \end{aligned}$$

where the last inequality follows from the Schwartz-Zippel lemma. □

3.3 Linear PCP for tensor checks

Definition 3.3.1. For a field $\mathbb{F}$, vectors $a \in \mathbb{F}^n$ and $b \in \mathbb{F}^m$, the tensor product $a \otimes b \in \mathbb{F}^{n \times m}$ is the matrix defined by

$$(a \otimes b)_{i,j} := a_i \cdot b_j \quad \forall i \in [n], j \in [m].$$

We write $\text{flat}(a \otimes b) \in \mathbb{F}^{n \cdot m}$ for the row-concatenation of $a \otimes b$.

For our purposes, we would love to test to check if $\text{flat}(a \otimes a) = b$

Definition 3.3.2. For a field $\mathbb{F}$ and $n \in \mathbb{N}$, define the tensor test language

$$\text{TENSORQ}(\mathbb{F}, n) := \{(a, b) \in \mathbb{F}^n \times \mathbb{F}^{n^2} \mid b = \text{flat}(a \otimes a)\}.$$

Theorem 3.3.3. For every finite field $\mathbb{F}$ and $n \in \mathbb{N}$,

$$\text{TENSORQ}(\mathbb{F}, n) \in \text{LPCP} \left[\varepsilon_c = 0, \varepsilon_s = \frac{2|\mathbb{F}| - 1}{|\mathbb{F}|^2}, \Sigma = \mathbb{F}, \ell = n + n^2, q = 3, r = 2n \cdot \log(|\mathbb{F}|) \right].$$

Proof. Consider the following LPCP verifier $V^{\langle a, \cdot \rangle, \langle b, \cdot \rangle}$ proceeds as follows:

1. Sample $s, t \leftarrow \mathbb{F}^n$.
2. Query a at s and at t , obtaining $\langle a, s \rangle$ and $\langle a, t \rangle$.
3. Query b at $\text{flat}(s \otimes t)$, obtaining $\langle b, \text{flat}(s \otimes t) \rangle$.
4. Check if $\langle b, \text{flat}(s \otimes t) \rangle = \langle a, s \rangle \cdot \langle a, t \rangle$.

Completeness. Suppose $b = \text{flat}(a \otimes a)$. Then $\forall s, t \in \mathbb{F}^n$,

$$\begin{aligned} \langle b, \text{flat}(s \otimes t) \rangle &= \langle \text{flat}(a \otimes a), \text{flat}(s \otimes t) \rangle = \sum_{i,j \in [n]} a_i a_j s_i t_j \\ &= \left(\sum_{i \in [n]} a_i s_i \right) \cdot \left(\sum_{j \in [n]} a_j t_j \right) = \langle a, s \rangle \cdot \langle a, t \rangle, \end{aligned}$$

Soundness. Suppose $b \neq \text{flat}(a \otimes a)$, i.e., there exists $i^*, j^* \in [n]$ such that $b_{i^* j^*} \neq a_{i^*} \cdot a_{j^*}$. For each $i \in [n]$ define the linear polynomial $p_i(t) := \sum_{j \in [n]} (b_{ij} - a_i a_j) t_j$. The check can be rewritten as

$$\langle b, \text{flat}(s \otimes t) \rangle - \langle a, s \rangle \langle a, t \rangle = \sum_{i \in [n]} \sum_{j \in [n]} (b_{ij} - a_i a_j) s_i t_j = \sum_{i \in [n]} p_i(t) s_i.$$

Immediate application of Polynomial Identity Testing yields a lower bound of $1 - \frac{2}{|\mathbb{F}|}$ but we can do better. Since $b_{i^* j^*} \neq a_{i^*} a_{j^*}$, the polynomial p_{i^*} is nonzero, so by the Schwartz-Zippel lemma applied to t ,

$$\Pr_t[p_{i^*}(t) \neq 0] \geq 1 - \frac{1}{|\mathbb{F}|}.$$

Conditioned on $p_{i^*}(t) \neq 0$, the expression $\sum_i p_i(t) s_i$ is a nonzero linear polynomial in s , so by the Schwartz-Zippel lemma applied to s ,

$$\Pr_{s \leftarrow \mathbb{F}^n} \left[\sum_i p_i(t) s_i \neq 0 \mid p_{i^*}(t) \neq 0 \right] \geq 1 - \frac{1}{|\mathbb{F}|}.$$

Hence

$$\Pr_{s,t}[\text{verifier rejects}] \geq \left(1 - \frac{1}{|\mathbb{F}|}\right)^2,$$

and therefore

$$\Pr_{s,t}[\text{verifier accepts}] \leq 1 - \left(1 - \frac{1}{|\mathbb{F}|}\right)^2 = \frac{2|\mathbb{F}| - 1}{|\mathbb{F}|^2}. \quad \square$$

Corollary 3.3.4.

$$\text{TensorQ}(\mathbb{F}_2, n) \in \text{LPCP}\left[\varepsilon_c = 0, \varepsilon_s = \frac{3}{4}, \Sigma = \mathbb{F}_2, \ell = n + n^2, q = 3, r = 2 \cdot n\right].$$

Proof. Immediate. $\square$

3.4 Linear PCP to PCP

Lemma 3.4.1 (Chernoff bound). *Let $X_1, \dots, X_N$ be independent random variables over $\{0, 1\}$, and let $\mu = \mathbb{E}\left[\sum_{i=1}^N X_i\right]$. For any $\Delta > 0$ one has*

$$\Pr\left[\sum_{i=1}^N X_i \geq \mu + \Delta\right] \leq \exp(-2\Delta^2/N)$$

Proof. Write $p_i = \mathbb{E}[X_i]$, so that $\mu = \sum_{i=1}^N p_i$. We first prove the elementary exponential-moment estimate

$$\mathbb{E}[\exp(\lambda(X_i - p_i))] \leq \exp(\lambda^2/8)$$

for every $\lambda > 0$ and every i . Since X_i is $\{0, 1\}$ -valued,

$$\mathbb{E}[\exp(\lambda(X_i - p_i))] = (1 - p_i) \exp(-\lambda p_i) + p_i \exp(\lambda(1 - p_i)).$$

Equivalently, it is enough to show

$$\log(1 - p_i + p_i \exp(\lambda)) - p_i \lambda \leq \lambda^2/8.$$

For $p \in [0, 1]$, set $f(\lambda) = \log(1 - p + p \exp(\lambda)) - p\lambda$. Then $f(0) = f'(0) = 0$, and

$$f''(\lambda) = \frac{p \exp(\lambda)}{1 - p + p \exp(\lambda)} \left(1 - \frac{p \exp(\lambda)}{1 - p + p \exp(\lambda)}\right) \leq \frac{1}{4}.$$

Hence, for $\lambda > 0$,

$$f(\lambda) = \int_0^\lambda \int_0^u f''(v) dv du \leq \int_0^\lambda \int_0^u \frac{1}{4} dv du = \lambda^2/8.$$

Let $S = \sum_{i=1}^N X_i$. By independence and the estimate above,

$$\mathbb{E}[\exp(\lambda(S - \mu))] = \prod_{i=1}^N \mathbb{E}[\exp(\lambda(X_i - p_i))] \leq \exp(N\lambda^2/8).$$

Markov's inequality gives, for every $\lambda > 0$,

$$\Pr[S \geq \mu + \Delta] = \Pr[\exp(\lambda(S - \mu)) \geq \exp(\lambda\Delta)] \leq \exp(-\lambda\Delta) \mathbb{E}[\exp(\lambda(S - \mu))]$$

Using the moment bound above, this is at most

$$\exp(-\lambda\Delta + N\lambda^2/8).$$

Taking $\lambda = 4\Delta/N$ gives

$$\Pr[S \geq \mu + \Delta] \leq \exp(-2\Delta^2/N).$$

□

Lemma 3.4.2.

$\text{LPCP}[\varepsilon_c, \varepsilon_s, \Sigma = \mathbb{F}_2, \ell, q, r] \subseteq \text{PCP}[\varepsilon_c, \varepsilon'_s = \max\{7/8, \varepsilon_s + 1/100\}, \Sigma' = \mathbb{F}_2, \ell' = 2^\ell, q' = 3 + 16\lceil \log(100q) \rceil q, r' = r]$

Proof. Let $L \in \text{LPCP}[\varepsilon_c, \varepsilon_s, \Sigma = \mathbb{F}_2, \ell, q, r]$, and let V be the LPCP verifier for L . Set $t = 8\lceil \log(100q) \rceil$, where $\log$ denotes the natural logarithm. We define a PCP verifier as follows, for any $\bar{p}i \in \mathbb{F}_2^{\ell/2}$ and $x \in \{0, 1\}^*$.

Verifier $\bar{V}^{\bar{\pi}}(x)$:

1. If $V_{\text{BLR}}^{\bar{\pi}} = 0$ output 0 and halt, otherwise proceed with the next step.
2. Independently for each $i \in [t]$, sample $r_i \leftarrow \mathbb{F}_2^\ell$.
3. Simulate V by answering each linear query a with $\text{plurality}(\bar{\pi}(a + r_i) - \bar{\pi}(r_i))_{i \in [t]}$.

Claim 3.4.3 (Completeness). *For every $x \in L$, there exists $\bar{\pi} \in \mathbb{F}_2^{\ell/2}$ such that $\Pr[\bar{V}^{\bar{\pi}}(x) = 1] \geq 1 - \varepsilon_c$.*

Proof. Since $x \in L$ and $L \in \text{LPCP}[\varepsilon_c, \varepsilon_s, \Sigma = \mathbb{F}_2, \ell, q, r]$, let $\pi \in \mathbb{F}_2^\ell$ such that $\Pr[V^{\langle \pi, \cdot \rangle}(x) = 1] \geq 1 - \varepsilon_c$. Then we construct $\bar{\pi} \in \mathbb{F}_2^{\ell/2}$ as follows: we define $\bar{\pi}(x) = \langle \pi, x \rangle$ for each $x \in \mathbb{F}^\ell$. Using the completeness of V_{BLR} we know that $V_{\text{BLR}}^{\bar{\pi}} = 1$ with probability 1. Also, $\text{plurality}(\bar{\pi}(a + r_i) - \bar{\pi}(r_i))_{i \in [t]} = \langle \pi, a \rangle$ for any query a and any r_i . We then conclude that $V^{\langle \pi, \cdot \rangle}(x) = \bar{V}^{\bar{\pi}}(x)$ for any $r_1, \dots, r_t$. Thus $\Pr[\bar{V}^{\bar{\pi}}(x) = 1] = \Pr[V^{\langle \pi, \cdot \rangle}(x) = 1] \geq 1 - \varepsilon_c$. □

Claim 3.4.4 (Soundness). *For every $x \notin L$ and every $\hat{\pi} \in \mathbb{F}_2^{\ell/2}$, one has $\Pr[\bar{V}^{\hat{\pi}}(x) = 1] \leq \max\{7/8, \varepsilon_s + 1/100\}$.*

Proof. Let $x \notin L$ and $\hat{\pi} \in \mathbb{F}_2^{\ell/2}$. We consider two cases.

Case $\delta(\hat{\pi}, \text{LIN}) \geq 1/8$. Using the soundness of V_{BLR} , we know that $\Pr[V_{\text{BLR}}^{\hat{\pi}} = 0] \geq 1/8$. Since $\Pr[\bar{V}^{\hat{\pi}}(x) = 1] \leq \Pr[V_{\text{BLR}}^{\hat{\pi}} = 1]$ we conclude $\Pr[\bar{V}^{\hat{\pi}}(x) = 1] \leq 1 - 1/8 = 7/8$.

Case $\delta(\hat{\pi}, \text{LIN}) < 1/8$ Let $S = \{\tilde{\pi} \in \mathcal{LJN} : \delta(\hat{\pi}, \tilde{\pi}) \leq \delta(\hat{\pi}, \text{LIN})\}$. Suppose for a contradiction that $|S| \geq 2$, and let $\bar{\pi}, \tilde{\pi} \in S$ be distinct: since $\delta(\hat{\pi}, \bar{\pi}) \leq \delta(\hat{\pi}, \text{LIN}) < 1/8$ and $\delta(\hat{\pi}, \tilde{\pi}) \leq \delta(\hat{\pi}, \text{LIN}) < 1/8$, by triangle inequality we have $\delta(\bar{\pi}, \tilde{\pi}) < 1/4$; since $|\mathbb{F}_2| = 2$, this contradicts the fact that any two distinct $\bar{\pi}, \tilde{\pi} \in \mathcal{LJN}$ satisfy $\delta(\bar{\pi}, \tilde{\pi}) \geq 1/2$.

Let then $\tilde{\pi}$ be the unique element of $\mathcal{LJN}$ with minimal distance to $\hat{\pi}$, and let $z \in \mathbb{F}^\ell$ the unique vector such that $\tilde{\pi}(x) = \langle z, x \rangle$ for all x . If for every query a that V asks we have $\text{plurality}(\hat{\pi}(a + r_i) - \hat{\pi}(r_i))_{i \in [t]} = \tilde{\pi}(a)$, then $\bar{V}^{\hat{\pi}}(x) = V^{\langle z, \cdot \rangle}(x)$, so provided that the r_i satisfy this condition we have that $\Pr[\bar{V}^{\hat{\pi}}(x) = 1] = \Pr[V^{\langle z, \cdot \rangle}(x) = 1] \leq \varepsilon_s$. We are only left to bound the probability that for each of the q queries that V asks we have $\text{plurality}(\hat{\pi}(a + r_i) - \hat{\pi}(r_i))_{i \in [t]} = \tilde{\pi}(a)$.

Note that for any a and r_i , if $\hat{\pi}(a+r_i) = \tilde{\pi}(a+r_i)$ and $\hat{\pi}(r_i) = \tilde{\pi}(r_i)$ then $\hat{\pi}(a+r_i) - \hat{\pi}(r_i) = \tilde{\pi}(a)$. Hence, the probability over one r_i that $\hat{\pi}(a+r_i) - \hat{\pi}(r_i) \neq \tilde{\pi}(a)$ is at most $2 \cdot \delta(\hat{\pi}, \tilde{\pi}) \leq 1/4$ by a union bound. Also note that $\text{plurality}(\hat{\pi}(a+r_i) - \hat{\pi}(r_i))_{i \in [t]} \neq \tilde{\pi}(a)$ means that $\hat{\pi}(a+r_i) - \hat{\pi}(r_i) \neq \tilde{\pi}(a)$ for at least $\lceil t/2 \rceil \geq t/2$ of the i 's. Let $X_i = \mathbb{1}[\hat{\pi}(a+r_i) - \hat{\pi}(r_i) \neq \tilde{\pi}(a)]$. Then $\mu = \mathbb{E}[\sum_{i \in [t]} X_i] \leq t/4$. Applying Chernoff bound with $\Delta = t/4$, the probability over the choice of $r_1, \dots, r_t$ that there are at least $t/2$ i 's with $X_i = 1$ is at most $\exp(-t/8)$. Union bounding over the q queries that V asks, we have that the local correction fails with probability at most $q \cdot \exp(-t/8) \leq 1/100$ by our choice of t . $\square$

$\square$

Theorem 3.4.5.

$$\text{QESAT}(\mathbb{F}_2, n) \in \text{LPCP}[\varepsilon_c = 0, \varepsilon_s = 3/4, \Sigma = \mathbb{F}_2, \ell = n + n^2, q = 4, r = |x| + 2 * n].$$

Proof. Let $(p_1, \dots, p_m)$ be an instance of $\text{QESAT}(\mathbb{F})$ with n variables.

The LPCP verifier expects a proof $\pi = (a, b) \in \mathbb{F}^{n+n^2}$ and works as follows:

Verifier $V^{(a,b)}(p_1, \dots, p_m)$:

1. Sample $r \leftarrow \mathbb{F}^m$ and $s, t \leftarrow \mathbb{F}^n$.
2. Define

$$M := \begin{bmatrix} \text{coeff}(p_1) \\ \vdots \\ \text{coeff}(p_m) \end{bmatrix} \in \mathbb{F}^{m \times (n+n^2)} \quad \text{and} \quad c := \begin{bmatrix} -\text{const}(p_1) \\ \vdots \\ -\text{const}(p_m) \end{bmatrix} \in \mathbb{F}^m.$$

(Note: $\text{coeff}(p_i) :=$ non-constant coeffs of p_i , and $\text{const}(p_i) :=$ constant coeff of p_i)

3. (linear equation test) $\rightarrow$ Query (a, b) at $M^T r$ and check that $\langle a \parallel b, M^T r \rangle = \langle c, r \rangle$.
4. (tensor test) $\rightarrow$ Query b at $\text{flat}(s \otimes t)$, a at s and t , and check that

$$\langle b, \text{flat}(s \otimes t) \rangle = \langle a, s \rangle \cdot \langle a, t \rangle.$$

Completeness: Suppose $p_1(a) = \dots = p_m(a) = 0$ and set $b := \text{flat}(a \otimes a)$.

Then

$$\Pr_{s,t} [\langle b, \text{flat}(s \otimes t) \rangle = \langle a, s \rangle \cdot \langle a, t \rangle] = 1$$

and

$$\Pr_r [\langle a \parallel b, M^T r \rangle = \langle c, r \rangle] = 1 \quad \left(\text{since } M \begin{bmatrix} a \\ \text{flat}(a \otimes a) \end{bmatrix} = c \right).$$

Soundness: Suppose $\forall a \in \mathbb{F}^n \exists i \in [m]$ s.t. $p_i(a) \neq 0$. Fix any $\pi = (a, b)$.

Either:

$$(i) \ b \neq \text{flat}(a \otimes a) \implies \text{tensor test passes w.p.} \leq \frac{2|\mathbb{F}|-1}{|\mathbb{F}|^2}$$

$$\text{OR (ii) } b = \text{flat}(a \otimes a) \text{ and } M \begin{bmatrix} a \\ b \end{bmatrix} \neq c \implies \text{linear equation test passes w.p.} \leq \frac{1}{|\mathbb{F}|}$$

$\square$
